Numbers, lists and tuples

Genome 559: Introduction to Statistical and Computational Genomics
Prof. James H. Thomas
Numbers

• Python defines various types of numbers:
  - Integer (1234)
  - Floating point number (12.34)
  - Octal and hexadecimal number (0177, 0x9gff)
  - Complex number (3.0+4.1j)

• You will likely only use the first two.
Conversions

```python
>>> 6/2
3

>>> 3.0/4.0
0.75

>>> 3/4.0
0.75

>>> 3*4.0
12.0

>>> 3*4
12

>>> 3/4
0
```

- The result of a mathematical operation on two numbers of the same type is a number of that type.
- The result of an operation on two numbers of different types is a number of the more complex type.

Watch out - result is truncated rather than rounded
Formatting numbers

- The `%` operator formats a number.
- The syntax is `<format> % <number>`

```python
>>> "%f" % 3  # print as float
'3.000000'
>>> "%2.f" % 3 # print as float with 2 digits after decimal
'3.00'
>>> "%5.2f" % 3 # width 5 characters
' 3.00'
```
Formatting codes

• `%d` = integer (d as in digit?)
• `%f` = float value (decimal number)
• `%e` = scientific notation
• `%g` = easily readable notation (i.e., use decimal notation unless there are too many zeroes, then switch to scientific notation)
More complex formats

`%[flags][width][.precision][code]`

- **Left justify** ("-")
- Include numeric sign ("+")
- Fill in with zeroes ("0")
- **Total width of output**
- **Number of digits after decimal**
- **d, f, e, g**
Examples

```python
>>> x = 7718
>>> "%d" % x
'7718'
>>> "%-6d" % x
'7718 '
>>> "%06d" % x
'007718'
>>> x = 1.23456789
>>> "%d" % x
'1'
>>> "%f" % x
'1.234568'
>>> "%e" % x
'1.234568e+00'
>>> "%g" % x
'1.23457'
>>> "%g" % (x * 10000000)
'1.23457e+07'
```

Don’t worry if this all looks like Greek - you can figure out how to do these when you need them in your programs. After a while they are pretty easy.

It sure looks like Greek to me.

(It sure looks like to Greek to me)
Lists

• A list is an ordered set of objects

>>> myString = "Hillary"
>>> myList = ["Hillary", "Barack", "John"]

• Lists are
  - ordered left to right
  - indexed like strings (from 0)
  - mutable
  - possibly heterogeneous (including containing other lists)

>>> list1 = [0, 1, 2]
>>> list2 = ['A', 'B', 'C']
>>> list3 = ['D', 'E', 3, 4]
>>> list4 = [list1, list2, list3]  # WHAT?
>>> list4
[[0, 1, 2], ['A', 'B', 'C'], ['D', 'E', 3, 4]]
Lists and dynamic programming

# program to print scores in a DP matrix
dpm = [ [0,-4,-8], [-4,10,6], [-8,6,20] ]
print dpm[0][0], dpm[0][1], dpm[0][2]
print dpm[1][0], dpm[1][1], dpm[1][2]
print dpm[2][0], dpm[2][1], dpm[2][2]

> python print_dpm.py
0 -4 -8
-4 10 6
-8 6 20

this is called a 2-dimensional list (or a matrix or a 2-dimensional array)
More readable output

```python
# program to print scores in a matrix
dpm = [ [0,-4,-8], [-4,10,6], [-8,6,20] ]
print "%3d" % dpm[0][0], "%3d" % dpm[0][1], "%3d" % dpm[0][2]
print "%3d" % dpm[1][0], "%3d" % dpm[1][1], "%3d" % dpm[1][2]
print "%3d" % dpm[2][0], "%3d" % dpm[2][1], "%3d" % dpm[2][2]

> python print_dpm.py
  0  -4   -8
  -4  10   6
   -8  6  20
```

print integers with 3 characters each (default is right-justified)
Lists and strings are similar

**Strings**

```python
>>> s = 'A'+'T'+'C'+'G'
>>> s = "ATCG"

>>> print s[0]
A
>>> print s[-1]
G
>>> print s[2:]
CG

>>> s * 3
'ATCGATCGATCG'

>>> s[9]
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
IndexError: string index out of range
```

**Lists**

```python
>>> L = "adenine", "thymine"] + [
  "cytosine", "guanine"
]
>>> L = ["adenine", "thymine",
  "cytosine", "guanine"]

>>> print L[0]
adene
>>> print L[-1]
guaine
>>> print L[2:]
['cytosine', 'guanine']

>>> L * 3
['adenine', 'thymine', 'cytosine',
  'guanine', 'adenine', 'thymine',
  'cytosine', 'guanine', 'adenine',
  'thymine', 'cytosine', 'guanine']

>>> L[9]
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
IndexError: list index out of range
```

(you can think of a string as an **immutable list** of characters)
Lists can be changed; strings are immutable.

**Lists**

```python
>>> L = ["adenine", "thymine", "cytosine", "guanine"]
>>> print L
['adenine', 'thymine', 'cytosine', 'guanine']
>>> L[1] = "uracil"
>>> print L
['adenine', 'uracil', 'cytosine', 'guanine']
>>> L.reverse()
>>> print L
['guanine', 'cytosine', 'uracil', 'adenine']
>>> del L[0]
>>> print L
['cytosine', 'uracil', 'adenine']
```

**Strings**

```python
>>> s = "ATCG"
>>> print s
ATCG
>>> s[1] = "U"
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
TypeError: object doesn't support item assignment

>>> s.reverse()
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
AttributeError: 'str' object has no attribute 'reverse'
```
More list operations and methods

```
>>> L = ['thymine', 'cytosine', 'guanine']
>>> L.insert(0, 'adenine')                      # insert before position 0
>>> print L
['adenine', 'thymine', 'cytosine', 'guanine']
>>> L.insert(2, 'uracil')
>>> print L
['adenine', 'thymine', 'uracil', 'cytosine', 'guanine']
>>> print L[:2]
['adenine', 'thymine']
>>> L[:2] = ['A', 'T']                          # replace elements 0 and 1
>>> print L
['A', 'T', 'uracil', 'cytosine', 'guanine']
>>> L[:2] = []                                  # replace elements 0 and 1 with nothing
>>> print L
['uracil', 'cytosine', 'guanine']
>>> L = ['A', 'T', 'C', 'G']
>>> L.index('C')                                # find index of first list element that is the same as 'C'
2
>>> L.remove('C')                               # remove first element that is the same as 'C'
>>> print L
['A', 'T', 'G']
```
Methods for expanding lists

```python
>>> data = []
# make an empty list
>>> print data
[]
>>> data.append("Hello!")
# append means "add to the end"
>>> print data
["Hello!"]
>>> data.append(5)
>>> print data
["Hello!", 5]
>>> data.append([9, 8, 7])
# append a list to end of the list
>>> print data
["Hello!", 5, [9, 8, 7]]
>>> data.extend([4, 5, 6])
# extend means append each element
>>> print data
["Hello!", 5, [9, 8, 7], 4, 5, 6]
>>> print data[2]
[9, 8, 7]
>>> print data[2][0]
9
```

notice that this list contains three different types of objects: a string, some numbers, and a list.
Turn a string into a list

`string.split(x)` or `list(S)`

```python
>>> protein = "ALA PRO ILE CYS"
>>> residues = protein.split()  # split() uses whitespace
>>> print residues
['ALA', 'PRO', 'ILE', 'CYS']
>>> list(protein)  # list explodes each char
>>> print protein.split()  # the list hasn't changed
['ALA', 'PRO', 'ILE', 'CYS']
>>> protein2 = "HIS-GLU-PHE-ASP"
>>> protein2.split("-")  # split at every "-" character
['HIS', 'GLU', 'PHE', 'ASP']
```
**Turn a list into a string**

`join` is the opposite of `split`:

```python
<delimiter>.join(L)
```

```python
>>> L1 = ["Asp", "Gly", "Gln", "Pro", "Val"]
>>> print "-".join(L1)
Asp-Gly-Gln-Pro-Val
>>> print "**".join(L1)
Asp**Gly**Gln**Pro**Val
>>> L2 = "\n".join(L1)
>>> L2
'Asp\nGly\nGln\nPro\nVal'
>>> print L2
Asp
Gly
Gln
Pro
Val
```

- the order is confusing.
- string to join with is first.
- list to be joined is second.
**Tuples: immutable lists**

Tuples are immutable. Why? Sometimes you want to guarantee that a list won’t change.

Tuples support operations but not methods.

```python
>>> T = (1,2,3,4)
>>> T*4
(1, 2, 3, 4, 1, 2, 3, 4, 1, 2, 3, 4, 1, 2, 3, 4)
>>> T + T
(1, 2, 3, 4, 1, 2, 3, 4)
>>> T
(1, 2, 3, 4)
>>> T[1] = 4
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
TypeError: object doesn't support item assignment
>>> x = (T[0], 5, "eight")
>>> print x
(1, 5, 'eight')
>>> print y.reverse()
('eight', '5', '1')
>>> z = tuple(y)  # converts a list to a tuple
```
Basic list operations:

L = ['dna','rna','protein']  # list assignment
L2 = [1,2,'dogma',L]        # list hold different objects
L2[2] = 'central'           # change an element (mutable)
L2[0:2] = 'ACGT'            # replace a slice
del L[0:1] = 'nucs'         # delete a slice
L2 + L                      # concatenate
L2*3                        # repeat list
L[x:y]                      # define the range of a list
len(L)                      # length of list
''.join(L)                  # convert a list to string
S.split(x)                  # convert string to list- x delimited
list(S)                     # convert string to list - explode
list(T)                     # converts a tuple to list

Methods:

L.append(x)                 # add to the end
L.extend(x)                 # append each element from x to list
L.count(x)                  # count the occurrences of x
L.index(x)                  # give element location of x
L.insert(i,x)               # insert at element x at element i
L.remove(x)                 # delete first occurrence of x
L.pop(i)                    # extract element l
L.reverse()                 # reverse list in place
L.sort()                    # sort list in place
Reminder - linked from the course web site is a Python cheat sheet that contains most of the basic information we are covering in a short reference format.
Sample problem #1

- Write a program called dna-composition.py that takes a DNA sequence as the first command line argument and prints the number of A's, C's, G's and T's.

> python dna-composition.py ACGTGCGTTAC
2 A’s
3 C’s
3 G’s
3 T’s
import sys
sequence = sys.argv[1].upper()
print sequence.count('A'), "A's"
print sequence.count('C'), "C's"
print sequence.count('G'), "G's"
print sequence.count('T'), "T's"

Note - this uses the trick that you can embed single quotes inside a double-quoted string (or vice versa) without using an escape code.
Sample problem #2

- The object `sys.argv` is a list of strings.
- Write a program `reverse-args.py` that removes the program name from the beginning of this list and then prints the remaining command line arguments (no matter how many of them are given) in reverse order with asterisks in between.

```bash
> python reverse-args.py 1 2 3
3*2*1
```
import sys
args = sys.argv[1:]
args.reverse()
print "*".join(args)
Sample problem #3

- The melting temperature of a primer sequence (with its exact reverse complement) can be estimated as:

  \[ T = 2 \times (\text{# of A or T nucleotides}) + 4 \times (\text{# of G or C nucleotides}) \]

- Write a program `melting-temperature.py` that computes the melting temperature of a DNA sequence given as the first argument.

> python melting-temperature.py ACGGTCA
22
import sys
sequence = sys.argv[1].upper()
numAs = sequence.count('A')
numCs = sequence.count('C')
numGs = sequence.count('G')
numTs = sequence.count('T')
temp = (2 * (numAs + numTs)) + (4 * (numGs + numCs))
print temp
Challenge problem

Download the file "speech.txt" from the course web site. Read the entire file contents into a string, divide it into a list of words, sort the list of words, and print the list. Make the words all lower case so that they sort more sensibly (by default all upper case letters come before all lower case letters).

Tips:

To read the file as a single string use:

```python
speech_text = open("speech.txt").read()
```

To sort a list of strings use:

```python
string_list.sort()
```
speech_text = open("speech.txt").read()
# next line optional, just gets rid of common punctuation
speech_text = speech_text.replace("","").replace(".","")
speech_text = speech_text.lower()
wordList = speech_text.split()
wordList.sort()
print wordList
