## A quick review

- Trees:
- Represent sequence relationships
- A phylogenetic tree has a topology and branch lengths (distances)

- The number of tree topologies grows very fast with the number of species!
- Distance trees
- Compute pairwise corrected distances
- Build tree by sequential clustering algorithm (UPGMA or Neighbor-Joining).
- These algorithms don't consider all tree topologies, so they are very fast, even for large trees.

## "Maximum Parsimony Algorithm"

A fundamentally different method:
Instead of reconstructina a tree,
we will search for the best ree.

## (Maximum) Parsimony Principle

- "Pluralitas non est ponenda sine necessitate" (plurality should not be posited without necessity)

# Consider 4 species 

human<br>chimp<br>gorilla<br>orangutan

## Consider 4 species

## Sequence data:

```
human
chimp
gorilla
orangutan
```

- The same approach would work for any discrete property that can be associated with the various species:
- Gene content (presence/absence of each gene)
- Morphological features (e.g., "has wings", purple or white flowers)
- Numerical features (e.g., number of bristles)

## Consider 4 species

Sequence data:

## Parsimony Algorithm

1) Construct all possible trees
2) For each site in the alignment and for each tree count the minimal number of changes required
3) Add all sites up to obtain the total number of changes for each tree
4) Pick the tree with the lowest score
