Genome 559: Introduction to Statistical and Computational Genomics

Elhanan Borenstein

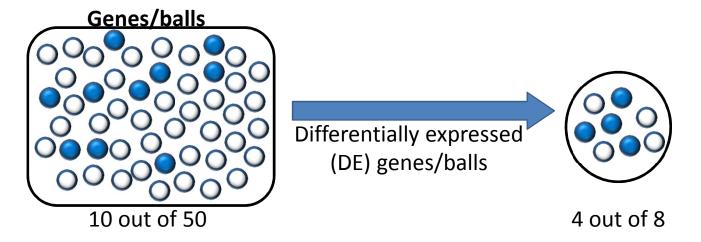

A quick review

- Gene expression profiling
 - Which molecular processes/functions are involved in a certain phenotype (e.g., disease, stress response, etc.)
- The Gene Ontology (GO) Project
 - Provides shared vocabulary/annotation
 - GO terms are linked in a complex structure
- Enrichment analysis:
 - Find the "most" differentially expressed genes
 - Identify functional annotations that are over-represented
 - Modified Fisher's exact test

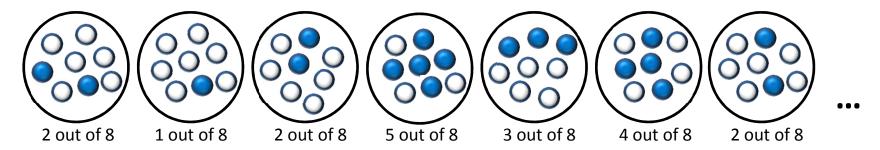

A quick review: Modified Fisher's exact test

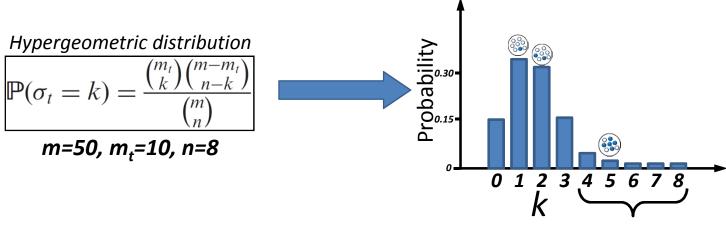

Do I have a surprisingly high number of blue genes?

Null model: the 8 genes/balls are selected randomly

So, if you have 50 balls, 10 of them are blue, and you pick 8 balls randomly, what is the probability that k of them are blue?

A quick review: Modified Fisher's exact test

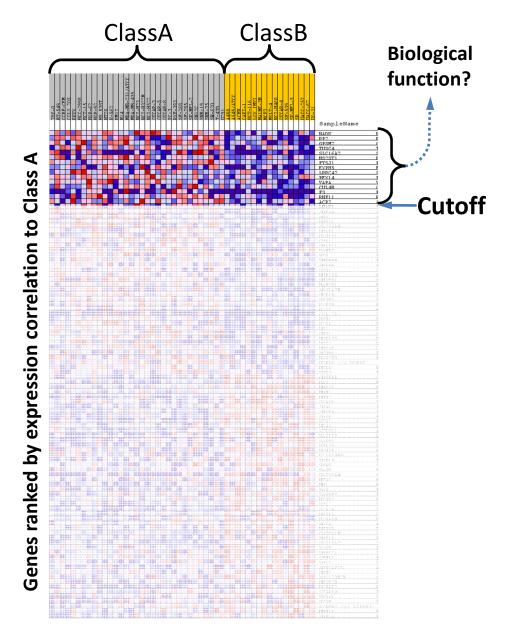

So ... do I have a surprisingly high_number of blue genes?

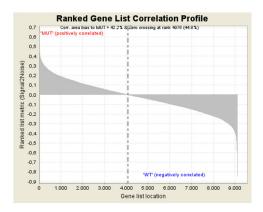

Can such high numbers (4 or above) occur by change?

What is the probability of getting at least 4 blue genes in the null model?

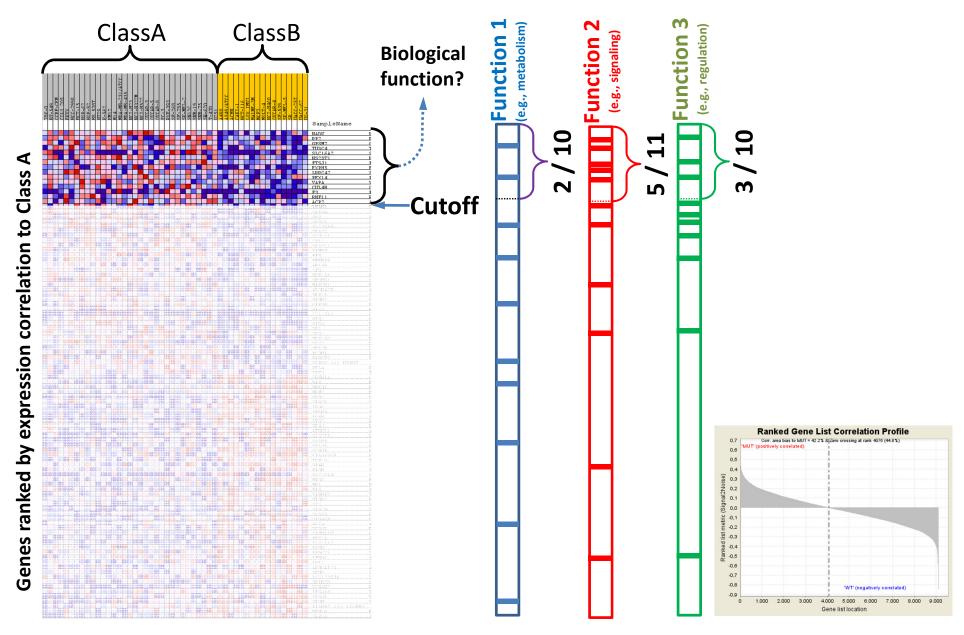

$$P(\sigma_t>=4)$$

Enrichment Analysis

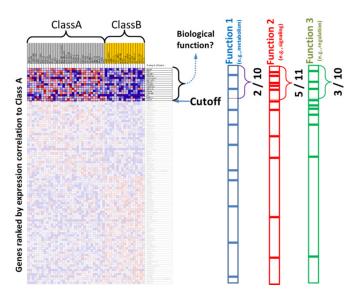

Enrichment Analysis

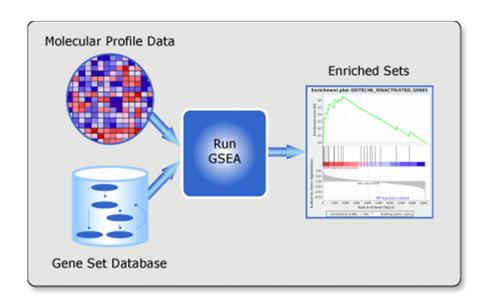

Problems with cutoff-based analysis

- After correcting for multiple hypotheses testing, no individual gene may meet the threshold due to noise.
- Alternatively, one may be left with a long list of significant genes without any unifying biological theme.
- The cutoff value is often arbitrary!
- We are really examining only a handful of genes, totally ignoring much of the data

Although genomiede BMA expression analysis has become a routine tool in biomedical research, extracting biological insight from such information remains a major challenge, Here, we describe a powerful analytical method called Gene Set Enrichment Analytic (GSAE) on temperature of the powerful analytical method called Gene Set Enrichment Analytic (GSAE) on temperature on the powerful analytical method called Gene Set Enrichment Analytic (GSAE) on temperature of the method offeres its power by focusing on gene sets, that is, groups of genes that these common biological functions, chromosomal focusion, or regulation. We demonstrate here GSAE yields ninglish mis severe to the properties of th reveals many biological pathways in common. The GSEA method is embodied in a freely available software package, together with an initial database of 1,325 biologically defined gene sets.

Genomewide expression analysis with DNA microarrays has become a mainstay of genomics research (1, 2). The challenge

no longer lies in obtaining gene expression profiles, but rather in interpreting the results to gain insights into biological mechanisms. In a typical experiment, mRNA expression profiles are generated for thousands of genes from a collection of samples belonging to In a typical experiment, MRNA expresses a passesses of for thousands of genes from a collection of samples belonging to one of two clauses, for example, tumors that are sensitive vs. resistant to a drug. The genes cam be ordered in a ranked list L₁ according to their differential expression between the clauses. The challenge is to extract mentaling from this list.

A common approach involves focusing on a handful of genes at to up and bottom of L (Le, thous howing the largest difference) to discern telltule biological clues. This approach has a few major limitations.

Expression and the clause distinction by using any satisfule metric (Fig. 14).

limitations.

(i) After correcting for multiple bypotheses testing, no individual gene may meet the threshold for statistical significance, because the relevant biological differences are modest relative to the noise inherent to the microurary technology.

(ii) Alternative, one may be left with a long list of statistically significant gene without any unifying biological theme. Interprevant of the property of t

area of expertise.

(iii) Single-gene analysis may miss important effects on pathways. Cellular processes often affect sets of genes acting in concert. An increase of 20% in all genes encoding members of a metabolic pathway may dramatically alter the flux through the pathway and purmony may cramatenessy area the first stronger for pattern any terms of my compensation of the same biological system, where different groups study the same biological system, who will be different groups study the same biological system, who will be a distributed by the different groups study the same biological system, who will be a compensation of the compensation of the compensation of the compensation of the same biological system, who will be contributed equally to the work distributed by the contributed equally to the work distributed by the contributed equally to the work of the contributed equally to the contributed equally to the work of the contributed equally to th

a method called Gene Set Enrichment Analysis (GSEA) that 0 2005 by The National Academy of Sciences of the USA

revealed that genes involved in oxidative phosphorylation show reduced expression in diabetics, shinough the servage decrease per gene is only 20%. The results from this study have been indepen-ently validated by other microury studies (3) and by in vio-functional studies (6). Given this success, we have developed GSIA into a robust technique for analyzing molecular profiling data. We studied its characteristics and performance and substantially revised and

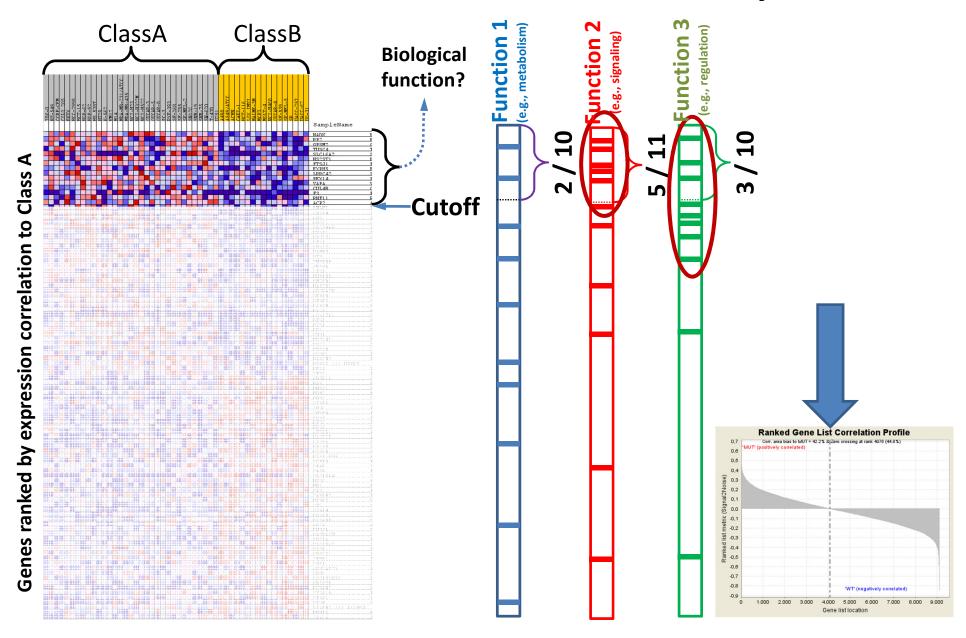

entracteristics and performance and sidestaminaly reviewed and generalized the original method for broader applicability. In this paper, we provide a full mathematical description of the OSEA methodology and dilustrate its suffity by applying it to several diverse biological problems. We have also created a software package, called OSEAP and an initial inventory of gene sets

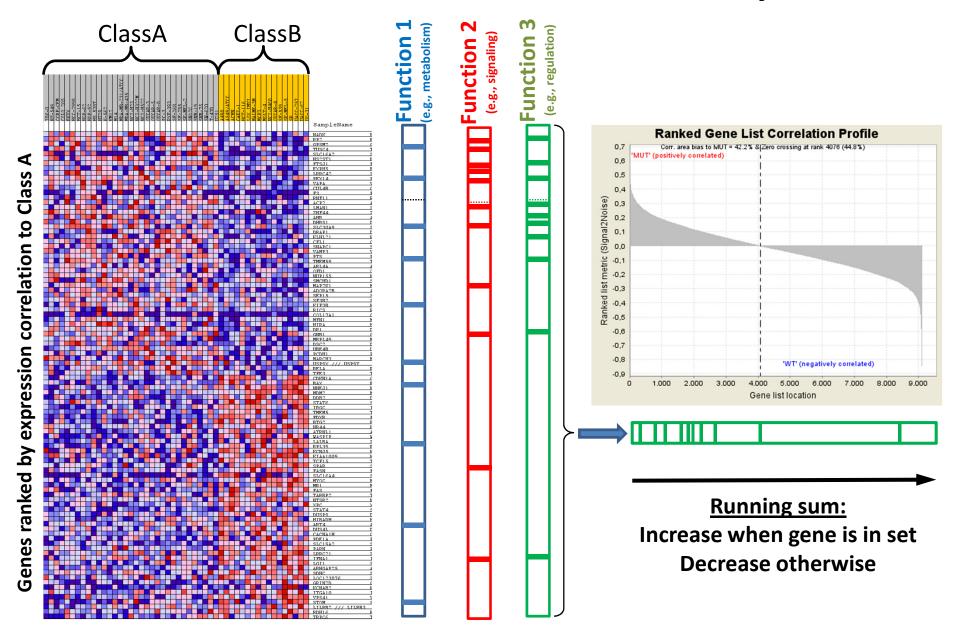

Given an a priori defined set of genes S (e.g., genes encoding Given an a priori detined set of sgens S (e.g., genes encoung products in a metabolic pathway, located in the same cytogenetic band, or sharing the same GO category), the goal of GSEA is to determine whether the members of S are randomly distributed throughout L or primarily found at the top or bottom. We expect

PNAS | October 25, 2005 | vol. 102 | no. 43 | 15545-15550

GSEA key features

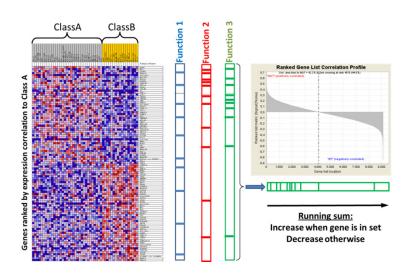

- Calculates a score for the enrichment of a entire set of genes rather than single genes!
- Does not require setting a cutoff!
- Identifies the set of relevant genes as part of the analysis!
- Provides a more robust statistical framework!

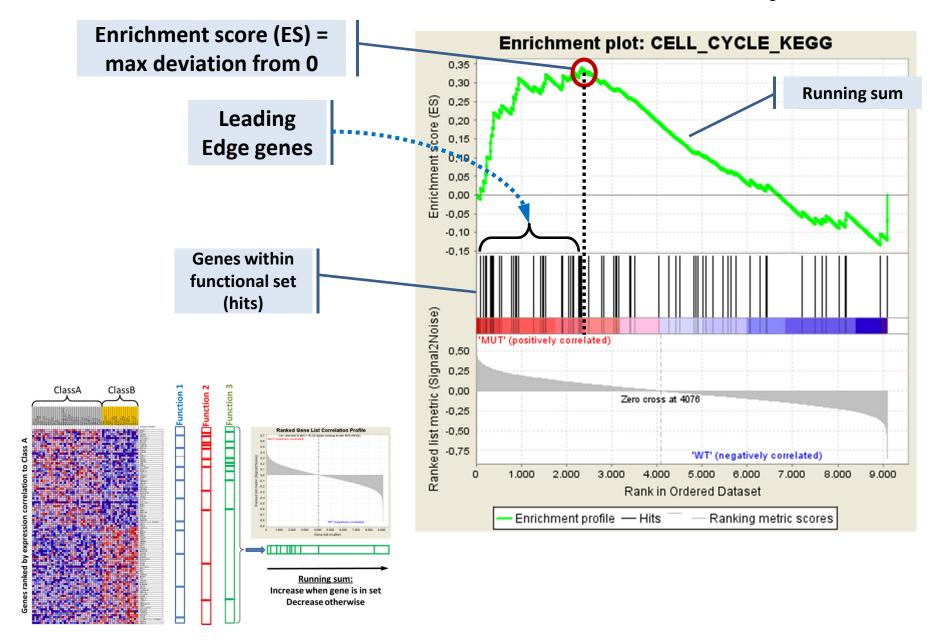

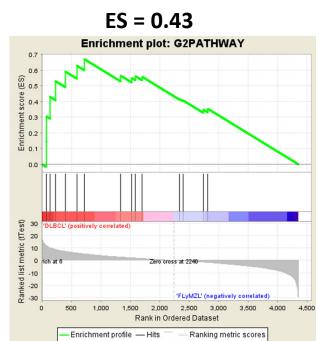

What would you expect if the hits were randomly distributed?

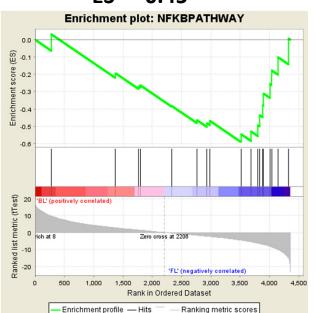

What would you expect if most of the hits cluster at the top of the list?

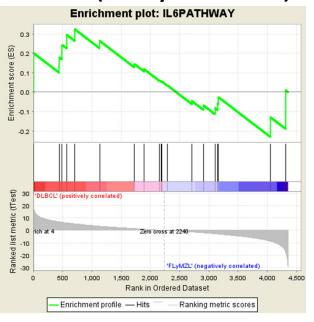

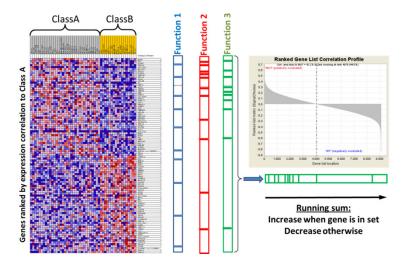

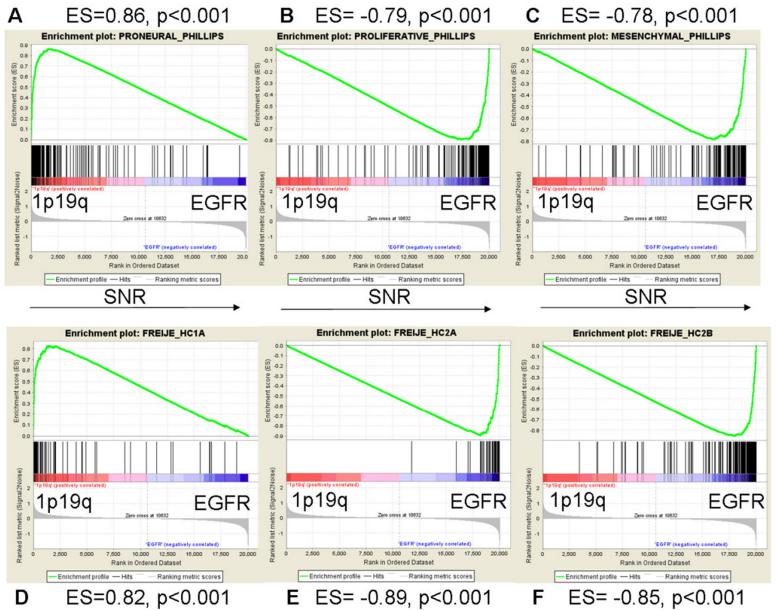

ES = -0.45

Low ES (evenly distributed)

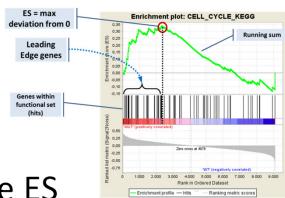

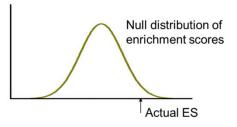

GSEA Steps

 Calculation of an enrichment score (ES) for each functional category

- 2. Estimation of significance level of the ES
 - An empirical permutation test
 - Phenotype labels are shuffled and the ES for this functional set is recomputed. Repeat 1000 times.
 - Generating a null distribution

- 3. Adjustment for multiple hypotheses testing
 - Necessary if comparing multiple gene sets (i.e., functions)
 - Computes FDR (false discovery rate)
